1. ABSTRACT

Recent research suggests that copper could be used as a novel selective target for cancer therapies. Copper is a co-factor essential for tumor angiogenesis processes and high levels of copper have been found in many types of human cancers, including prostate, breast and brain. We have reported that organic copper-containing compounds, such as 8-hydroxyquinoline-copper(II), are a novel class of proteasome inhibitors and tumor cell apoptosis inducers (Daniel et al., Biochem Pharmacol. 2004;67:1139-51). Most recently, we have found that when complexed with copper, the known antioxidant pyrrolidine dithiocarbamate (PDTC) forms a potent proteasome inhibitor in human breast cancer, but not normal cells (Daniel, Chen, et al., submitted). In the current study, we investigate whether the PDTC-copper complex can play similar roles in inhibiting the proteasomal activity and consequently inducing apoptosis in human prostate cancer cells. We used tetrathiomolybdate (TM), a strong copper chelator currently being tested in clinical trials, as a control. We report here that after binding to copper, PDTC, but not TM, can inhibit the proteasomal chymotrypsin-like activity, suppress proliferation, induce apoptotic cell death, and inhibit uptake of radiopharmaceutical 2-[18F]Fluoro-2-deoxy-D-glucose in cultured human prostate cancer cells. In contrast, PDTC, TM or copper alone or a TM-copper mixture had no such effects. Our study suggests that high copper levels in human prostate cancer in vivo can be targeted by a ligand such as PDTC, resulting in formation of an active proteasome inhibitor and apoptosis inducer specifically in prostate tumor, but not normal cells.
PDTC-copper complex as novel proteasome inhibitor and potential anti-cancer drug

Figure 1. Copper complex formation as indicated by color change. A. Chemical structure of PDTC. B. 50 mM of PDTC was mixed in a 1:1 molar ratio with CuCl₂. All solutions were made in DMSO. The appearance of intensified color of mixture indicated formation of copper complex.

2. INTRODUCTION

Copper is an essential trace metal for animals. The amount of copper in an organism is tightly regulated (1, 2). High levels of copper have been found in many types of human cancers including prostate, breast, colon, lung, and brain (3-11). Consistently, angiogenesis, the formation and differentiation of blood vessels, is essential for tumor growth, invasion, and metastasis (12-15). Indeed, molecular processes of angiogenesis require of copper, but not other trace metals, as an essential cofactor (12-21).

The ubiquitin/proteasome system plays an important role in the degradation of cellular proteins. This proteolytic system involves two distinct steps: ubiquitination and degradation (22, 23). The eukaryotic proteasome contains at least three known activities, which are associated with its β subunits. These are the chymotrypsin-like (cleavage after hydrophobic residues, β5 subunit), trypsin-like (cleavage after basic residues, β2 subunit), and caspase-like or peptidyl-glutamyl peptide-hydrolyzing (cleavage after acidic residues, β1 subunit) activities (24, 25). Inhibition of the proteasomal chymotrypsin-like, but not trypsin-like, activity has been found to be associated with induction of apoptosis in tumor cells (26-31).

Dithiocarbamates are a well-defined class of metal-chelating compounds. These compounds have been previously used for treating bacteria, fungi and AIDS (32, 33). Pyrrolidine dithiocarbamate (PDTC; Figure 1A), a member of the dithiocarbamates, is an antioxidant that has been found to be an effective chelator of heavy metals (34). Pyrrolidine dithiocarbamate (PDTC) is a known inhibitor of NFκB (35). It has been shown that PDTC is capable of binding copper, spontaneously forming a copper complex (36). PDTC and other dithiocarbamates have been found to induce apoptosis in conjunction with copper in different types of cancer cells (37, 38).

3. MATERIALS AND METHODS

3.1. Chemicals, reagents, and radiopharmaceuticals

Cupric chloride (CuCl₂), dimethyl sulfoxide (DMSO), pyrrolidine dithiocarbamate (PDTC), and ammonium tetrathiomolybdate (TM), 3-[4,5-Dimethylthiazol-2-yl]-2,5-diphenyl-tetrazolium bromide (MTT), and bisbenzimide Hoechst #33258 stain were all purchased from Sigma-Aldrich. The substrate for the chymotrypsin-like activity of the proteasome, Suc-Leu-Leu-Val-Tyr-AMC, was purchased from Calbiochem. Polyclonal antibody to poly(ADP-ribose) polymerase (PARP) was obtained from Boehringer, Mannheim. Monoclonal antiubiquitin antibody, secondary antibodies, anti-mouse IgG horseradish peroxidase, and anti-rabbit IgG-horseradish peroxidase were from Santa Cruz Biotechnology Inc. Radiopharmaceutical 2-[¹⁸F]Fluoro-2-deoxy-D-glucose ([¹⁸F]FDG), a tracer widely used for positron emission tomography (PET) imaging of cancers, is prepared by the method of Hamacher et al (43) using 1,3,4,6-tetra-O-acetyl-2-O-triflyl-β-D-manno-pyranose as the labeling precursor and ¹⁸F radioisotope produced with a cyclotron housed at the PET Center, Children’s Hospital of Michigan.

3.2. Preparation of the PDTC-Cu complex

To prepare PDTC-Cu complex, equal molar amounts of PDTC and CuCl₂, both dissolved in DMSO at 50 mM, were mixed by drop-wise addition of the CuCl₂ solution into the PDTC solution. The mixture was kept at room temperature for 10 minutes to allow formation of the PDTC-Cu complex. The freshly prepared PDTC-Cu complex was used for experiments.

The ubiquitin/proteasome system involves two distinct steps: ubiquitination and degradation (22, 23). The eukaryotic proteasome contains at least three known activities, which are associated with its β subunits. These are the chymotrypsin-like (cleavage after hydrophobic residues, β5 subunit), trypsin-like (cleavage after basic residues, β2 subunit), and caspase-like or peptidyl-glutamyl peptide-hydrolyzing (cleavage after acidic residues, β1 subunit) activities (24, 25). Inhibition of the proteasomal chymotrypsin-like, but not trypsin-like, activity has been found to be associated with induction of apoptosis in tumor cells (26-31).

Dithiocarbamates are a well-defined class of metal-chelating compounds. These compounds have been previously used for treating bacteria, fungi and AIDS (32, 33). Pyrrolidine dithiocarbamate (PDTC; Figure 1A), a member of the dithiocarbamates, is an antioxidant that has been found to be an effective chelator of heavy metals (34). Pyrrolidine dithiocarbamate (PDTC) is a known inhibitor of NFκB (35). It has been shown that PDTC is capable of binding copper, spontaneously forming a copper complex (36). PDTC and other dithiocarbamates have been found to induce apoptosis in conjunction with copper in different types of cancer cells (37, 38).

Tetrathiomolybdate (TM) is a copper chelator that was originally used for patients with Wilson’s disease (17, 18). TM has been found to be effective in impairing the growth of mammary tumors in HER2/neu transgenic mice (40) and lung metastatic carcinoma in C557BL6/J mice (41). In a phase I clinical trial with patients suffering from metastatic cancers, TM therapy achieved stable disease in 5 of 6 patients who became copper-deficient (20). However, the disease advanced in some other patients before copper levels were sufficiently lowered (17, 18, 20). These reports support the idea of copper control as an anticancer strategy.

We have previously demonstrated that certain types of copper-binding compounds are potent proteasome inhibitors (42). Most recently, we have also found that PDTC, after interacting with copper, forms a proteasome inhibitor in human breast cancer cells (Daniel KG, Chen D, Orlu S, Cui QC, Miller FR, Dou QP, submitted). In the current study, we investigated the effects of the PDTC-Cu complex in human prostate cancer cells. We report that PDTC is capable of binding copper, spontaneously forming a new complex that has proteasome-inhibitory and apoptosis-inducing activities to human prostate cancer cells. In contrast, copper, PDTC or TM alone, or TM-copper complex had no effects under the same experimental conditions. We propose that targeting highly elevated copper could be tumor-specific and that formation of an active proteasome inhibitory complex between PDTC and copper is a novel strategy that has great potential for prostate cancer therapies.
3.3. Cell culture, drug treatment and whole cell extract preparation
LNCaP human prostate cancer cell line was purchased from ATCC. Cell culture medium (RPMI 1640), antibiotics, and trypsin solution were purchased from Gibco. LNCaP cells were maintained in RPMI 1640 supplemented with 10% fetal calf serum, 100 units/mL of penicillin, 100 mg/mL of streptomycin and 10 mM HEPES at 37 °C in a humidified incubator with an atmosphere of 5% CO2. Cells were treated with noted molar amounts of compounds, mixtures, or with an equivalent volume of solvent control as indicated in the figure legends. Whole cell extracts were prepared as described previously (44, 45). Briefly, cells were harvested, washed with cold PBS twice, and homogenized in a lysis buffer (50 mM Tris–HCl, pH 8.0, 150 mM NaCl, 1% NP-40, 0.5 mM phenylmethylsulfonyl fluoride, and 0.5 mM dithiothreitol) for 30 min at 4 °C. Afterwards, the lysates were centrifuged at 12,000 g for 15 min, and the supernatants were collected as whole cell extract.

3.4. Cell proliferation inhibition assay
The effects of each compound and their copper mixtures on LNCaP cells were determined using the MTT dye uptake method. Briefly, LNCaP cells (10^4/well/0.1 ml) were seeded in triplicate in a 96-well plate and incubated at 37 °C in a humidified incubator with an atmosphere of 5% CO2 until 70-80% confluence. This was followed by an additional 24-h incubation with fresh medium containing different concentrations of each compound, mixtures, or copper mixtures. The same amount of DMSO was added as the solvent control. Thereafter, 100 µL MTT solution (1 mg/ml in serum-free medium) replaced the medium in each well. After 4 h at 37 °C incubation, the MTT solution was replaced by 100 µL DMSO. When the blue crystals were dissolved, the optical density (OD) was measured in a Wallac Victor3™ multilabel plate reader (Perkin Elmer, USA) at a wavelength of 560 nm. The formula used to evaluate the result is as follows: inhibition of cell proliferation (%) = (OD of the experimental samples/OD of the control)×100%.

3.5. Cellular and nuclear morphology analysis
LNCaP cells were treated as indicated (see figure legends). Afterwards, the cells were visualized by microscopic imaging with either phase contrast for cellular morphology or Hoechst staining with fluorescence for nuclear morphology. Briefly, the cells were washed with PBS and fixed in 75% ethanol for at least 1 h at 4 °C followed by washing with PBS three times and staining in 50 µM of Hoechst 33258 for 30 min at 4 °C in dark. Subsequently the cells were washed and resuspended in 50 µL PBS and mounted for viewing. Copper mixture-induced apoptosis was monitored by the extent of nuclear fragmentation. Nuclear fragmentation was visualized by Hoechst 33258 staining of apoptotic nuclei using Zeiss Axiovision fluorescence microscope (Carl Zeiss Microscope Inc., Hallbergmoos, Germany).

3.6. In vitro proteasome activity assay
The cell-free chymotrypsin-like activity of the proteasome was determined by measuring the release of the AMC groups from a substrate as previously described (26). Briefly, after each treatment, whole cell extract (10 µg) of LNCaP cells was incubated in 100 µl of assay buffer (50 mM Tris–HCl, pH 7.5) and 40 µM fluorogenic peptide substrates, Suc-Leu-Leu-Val-Tyr-AMC for the chymotrypsin-like activity for 1 h at 37 °C. After incubation, production of hydrolyzed AMC groups was measured using a Wallac Victor3™ multilabel plate reader with an excitation filter of 380 nm and an emission filter of 460 nm. Changes in fluorescence were calculated against non-treated controls and plotted with statistical analysis using Microsoft Excel™ software.

3.7. Western Blot Assay
To evaluate ubiquitinated protein accumulation and PARP cleavage induced by PDTC-Cu complex treatment, cell lysates (30 µg) from treated LNCaP cells were subject to SDS–PAGE analysis and then transferred to a nitrocellulose membrane. The Western blot analysis was performed using specific antibodies to ubiquitin and PARP as described previously (42, 45), followed by visualization with an enhanced chemiluminescence (ECL) (Amersham Biosciences).

3.8. Cellular 18F-FDG uptake assay
To evaluate the effects of PDTC-Cu complex on cellular uptake of 18F-FDG, LNCaP cells (5x10^5 cells in 1 ml of RPMI1640/well) were seeded in triplicate on a 12-well cell culture plate 12 hours prior to treatment of cells with PDTC-Cu complex and other control reagents. Following treatment for 12 hours, LNCaP cells were incubated with 5 µCi (185 kBq) of 18F-FDG added in the cell culture medium for 1 hour at 37 °C, in an atmosphere containing 5% CO2. At end of incubation, the culture medium containing 18F-FDG was removed and the cells were washed with PBS three times. Subsequently, the cells were digested with 5% trypsin solution and collected in a tube for radioactivity count using a Packard RiaStar multiwell gamma counter (Packard Instrument Co, Meriden CT). Radioactivity of the cells was calculated as percentage of inoculation dose (ID%) normalized to cell number (5x10^5/well), in reference to radioactivity of 5 µCi (185 kBq) of 18F-FDG.

3.9. Statistical analysis
All data were expressed as mean ±SD. Statistical analysis was performed with the paired, two-tailed T test using Microsoft Excel software and p values < 0.05 or < 0.01 were considered to represent statistical significance.

4. RESULTS
4.1. PDTC spontaneously reacts with copper to form a new complex
In order to use endogenous elevated copper in prostate tumor tissues as a targeting mechanism for cancer therapy, it is prerequisite for a ligand to react spontaneously with copper to form a new complex. To test the reactivity of PDTC with copper, 50 mM of PDTC was added to a 50 mM of copper (II) chloride (Figure 1). The reaction of PDTC with copper results in a dramatic color change (Figure 1), indicating formation of a new metal complex.
PDTC-copper complex as novel proteasome inhibitor and potential anti-cancer drug

2.935

4.2. The PDTC-Cu complex inhibits the chymotrypsin-like activity of the proteasome in intact LNCaP cells

Previously we reported that organic copper complexes inhibit the cellular proteasomal activity (42; Daniel KG, Chen D, Orlu S, Cui QC, Miller FR, Dou QP, submitted). We then investigated whether the PDTC-copper could inhibit the proteasome activity in human prostate cancer cell. Prostate cancer LNCaP cells were treated for 24 h with copper, PDTC, or PDTC-copper mixture, using TM and TM-copper mixture as controls. After treatment, the cells were collected and protein extracts were prepared for analysis of proteasome inhibition. Inhibition of the proteasome was measured by two assays: the chymotrypsin-like activity assay (Figure 2A), and the accumulation of ubiquitinated proteins by Western blotting (Figure 2B). We found that the prepared PDTC-copper mixture significantly inhibited the proteasome activity in LNCaP cells, as indicated by low levels of the proteasomal chymotrypsin-like activity (Figure 2A) and accumulation of ubiquitinated proteins (Figure 2B, lane 5). Copper or PDTC alone does not inhibit the proteasome activity (Figure 2A, B, lanes 2, 3). We found that neither TM nor the TM-Cu mixture was able to inhibit the proteasome activity in the prostate cancer cells (Figure 2), further supporting that TM acts as a passive copper chelator and eliminato and TM-copper is an inactive complex (42). These data support the hypothesis that a PDTC-Cu complex is capable of proteasome inhibition.

4.3. PDTC-Cu mixture effectively inhibits proliferation of human prostate cancer cells

Since PDTC can form a complex with copper, as indicated by color change (Figure 1), and is able to inhibit the proteasomal activity in prostate cancer cells (Figure 2), we then tested whether the complex is able to inhibit proliferation of human prostate cancer cells. Prostate cancer LNCaP cells were treated with copper, PDTC, PDTC-copper mixture, TM or TM-copper mixture for 24 h. We found that the PDTC-copper mixture inhibited LNCaP cell proliferation in a dose-dependent manner (Figure 3). The PDTC-copper mixture showed 50% inhibition at 1 µM and greater than 90% inhibition at 5-10 µM (Figure 3). The IC50 value of the PDTC-copper mixture was determined as 1 ±0.07 µM. In contrast, copper alone, PDTC alone, or TM and TM mixed with copper had no significant effect (Figure 3).

4.4. LNCaP cells treated with the PDTC-Cu complex undergo apoptosis

Having demonstrated that the PDTC-copper complex is capable of inhibiting cellular proliferation in prostate cancer cells (Figure 3), we then determined whether this mixture could induce prostate cancer cell apoptosis. Exponentially growing LNCaP cells were treated with copper, PDTC, TM or their mixtures for 24 h, followed by observing cellular and nuclear morphological changes by phase contrast or fluorescence microscope, respectively (Figure 4). The cells treated with the PDTC-copper mixture became spherical and detached (Figure 4A). By staining with Hoescht 33258, the most of the nuclei in the PDTC-copper-treated cells were brighter and denser, compared to those treated with copper, PDTC, TM alone or TM-copper (Figure 4B). These results suggested that the cells treated with the PDTC-copper mixture were undergoing apoptosis. Apoptosis induction was further verified by cleavage of PARP (Figure 2C). Treatment with

This result is consistent with a previous publication showing that PDTC is strong copper chelator (37). Therefore, PDTC may be capable of combining with endogenous copper in tumor tissues and forming an active proteasome-inhibitory complex.
Figure 3. Anti-proliferative effects of the PDTC-copper mixture. LNCaP cells were treated for 24 h with the following: copper (Cu; at 30 \( \mu \)M), PDTC (P; 10 \( \mu \)M), TM (T; 30 \( \mu \)M), PDTC-copper (PDTC-Cu; 1, 5, 10 \( \mu \)M), or TM-copper (TM-Cu; 10, 20, 30 \( \mu \)M). After 24 h the media was removed and cells were treated with MTT solution as described in Materials and Methods. Measurement of MTT conversion by absorbance at 560 nm showed that LNCaP cells responded in a dose-dependent manner to PDTC-copper mixture but not to TM-copper mixture. (* \( P < 0.05; \) ** \( P < 0.01 \))

Figure 4. Cellular and nuclear morphological changes indicate induction of apoptosis by PDTC-copper mixture in LNCaP cells.

4.5. Reduction of F18-FDG uptake by LNCaP cells after treatment with PDTC-Cu complex

To prepare for evaluation of anti-tumor activity of the PDTC-Cu complex in vivo with \(^{18}\)F-FDG PET imaging, we tested effects of the PDTC-Cu complex on \(^{18}\)F-FDG uptake by LNCaP cells following treatment with the PDTC-Cu complex in vitro (Figure 5). Cellular \(^{18}\)F-FDG uptake was dramatically reduced in LNCaP cells treated with 10 \( \mu \)M of the PDTC-Cu complex (ID% 0.05), in comparison to LNCaP cells treated with 10 \( \mu \)M PDTC (ID% 0.70), 10 \( \mu \)M copper chloride (ID% 0.74), 5\% DMSO (ID% 0.94), or no treatment (ID% 1.02) (Figure 5).

5. DISCUSSION

In regards to the current anti-cancer chemotherapies, most drugs used in clinics are toxic to some extent. This is mainly due to their inability to distinguish normal cells from tumor cells. In order to eliminate toxicity, it is necessary to identify some specific properties or features of cancer cells different from normal cells. An increased understanding of the tumor-specific differences will facilitate the development of novel anti-cancer drugs that selectively kill cancer cells with limited toxicity or no toxicity to the normal cells.

One such difference is the ubiquitin-proteasome pathway. In cancer cells, dysregulation of this system plays a critical role for tumor progression, drug resistance and altered immune surveillance (46). Previously we reported that proteasome inhibitors induce apoptosis selectively in tumor cells but not in normal cells (47). Bortezomib, the first proteasome inhibitor as a potential anticancer drug, is currently being tested in phase III clinical trials (48, 49). Another attractive tumor-specific feature is high levels of copper found in many types of human cancers including prostate, breast, colon, lung, and brain (3-11). Molecular processes of angiogenesis include: the requirement of copper, but not other trace metals, as an essential cofactor, stimulation of endothelial growth by tumor cytokine production (i.e., vasoendothelial growth factor), degradation of extracellular matrix proteins by metalloproteinases, and migration of endothelial cells mediated by integrins (12-21).

It has been shown that cancer cells are more sensitive to proteasome inhibition than normal cells (27, 47, 50-52). We hypothesize that an inactive or nontoxic organic ligand could bind with elevated copper found in tumor tissues and result in a complex capable of proteasome inhibition. After the ligand binds with endogenous tumor cellular copper, the formed complex would inhibit the proteasome activity, leading to inhibition of the processes of angiogenesis in tumor tissues and induction of apoptosis in the tumor cells.

In search for new proteasome inhibitors of high potency and low toxicity, we found that several organic copper complexes possessing potent proteasome-inhibitory and apoptosis-inducing activities in tumor but not in normal cells (42). Since PDTC, an antioxidant used to treat inflammation, atherosclerosis and metal intoxication (34,
PDTC-copper complex as novel proteasome inhibitor and potential anti-cancer drug

Figure 5. Cellular 18F-FDG uptake assay on LNCaP cells treated with PDTC-Cu complex. Cellular uptake of 18F-FDG was dramatically reduced in LNCaP cells treated with the PDTC-Cu complex in comparison to controls. PDTC, pyrrolidine dithiocarbamate; DMSO, dimethyl sulfoxide; Cu, copper chloride; NT, no treatment, Isotope Uptake ID%, percentage of inoculation dose of 18F-FDG.

Once we verified that PDTC could spontaneously bind with copper and form a new complex (Figure 1), we then tested the complex in LNCaP cells to determine whether or not the complex was a proteasome inhibitor. We examined both cellular proteasome activity (Figure 2A) and accumulation of ubiquitinated proteins (Figure 2B). We found that the cells treated with PDTC-copper mixture had significantly reduced chymotrypsin-like activity (Figure 2A) and accumulation of ubiquitinated proteins (Figure 2B), indicating that proteasome inhibition had occurred. In contrast, copper, PDTC alone, TM alone, or TM mixed with copper was incapable of inhibiting the proteasome (Figure 2A and B).

We then tested whether or not the complex was capable of inhibiting proliferation of human prostate cancer cells. The results showed that only PDTC-copper mixture could inhibit proliferation of LNCaP cells in dose-dependent manner, but not copper, PDTC alone, TM alone, or TM-copper mixture (Figure 3).

Afterward we verified the association between PTDC-copper induced inhibition of proteasomal activity and proliferation, we then determined apoptosis-inducing activities of each compound in prostate cancer cells. Our result demonstrated that LNCaP cells treated with PDTC-copper mixture underwent apoptosis, as showed by PARP cleavage (Figure 2C) and cellular (Figure 4A) and nuclear (Figure 4B) morphological changes. However, LNCaP cells treated with copper, PDTC alone, TM alone, or TM-copper mixture failed to undergo apoptosis (Figs. 2C, 4A and B).

The data presented here supports the novel concept of using accumulated copper in prostate cancer cells and tissues as a selection method for chemotherapy. Nontoxic organic compounds such as PDTC can spontaneously bind with tumor cellular copper and form a proteasome inhibitor and an apoptosis inducer. PDTC has been previously explored for use in other diseases and we believe our data support further investigation of this and other similar compounds in an anticopper/anticancer strategy.

6. ACKNOWLEDGEMENTS

This work is supported in part by research grants from the National Cancer Institute-National Institutes of Health, the United States Army Medical Research and Material Command, and Barbara Ann Karmanos Cancer Institute Prevention Program (to Q. P. D.). The authors thank Dr. Thomas Mangner for preparation of radiopharmaceutical 18F-FDG.
